What you need to know to get a nearly peak FLOPS

- so you now know how to use multicores and SIMD instructions
- they are two key elements to get a nearly peak FLOPS
- the last key element: Instruction Level Parallelism (ILP) of superscalar processors

Contents

- Introduction
- 2 An endeavor to nearly peak FLOPS
- 3 Latency limit
- 4 Overcoming latency
- 5 Superscalar processors
- 6 A simple yet fairly fast single-core matrix multiply

An endeavor to nearly peak FLOPS

• measure how fast we can iterate the following loop (a similar experiment we did on GPU)

```
floatv a, x, c;
for (i = 0; i < n; i++) {
    x = a * x + c;
}</pre>
```

• the code performs $L \times n$ FMAs and almost nothing else (L = the number of lanes in a single SIMD variable)

Assembly

```
.LBB3_8:
vfmadd213pd %zmm1, %zmm0, %zmm2
addq $-8, %rax
jne .LBB3_8
```

- the loop is unrolled eight times
- why does it take > 3 cycles to do a single fmadd?

Latency and throughput

- our core (Ice Lake) can execute *two* fmadd *instructions every* cycle
- but it does *not* mean the result of vfmadd at a line below is available in the next cycle for vfmadd at the next line

```
.LBB3_8:
1
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
5
      vfmadd213pd %zmm1, %zmm0, %zmm2
6
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
8
      vfmadd213pd %zmm1, %zmm0, %zmm2
      addq $-8, %rax
10
      jne .LBB3_8
11
```

Latency and throughput

- our core (Ice Lake) can execute *two* fmadd *instructions every* cycle
- but it does *not* mean the result of vfmadd at a line below is available in the next cycle for vfmadd at the next line

```
.LBB3_8:
1
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
5
      vfmadd213pd %zmm1, %zmm0, %zmm2
6
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      vfmadd213pd %zmm1, %zmm0, %zmm2
      addq $-8, %rax
10
      jne .LBB3_8
11
```

- what you need to know:
 - "two vfmadd instructions every cycle" refers to the throughput
 - each instruction has a specific *latency* (≥ 1 cycle)

Latencies/throughput

instruction	Haswell	Broadwell	Skylake
fp add	3	3	4/2
fp mul	5	3	4/2
fp fmadd	5	5	4/2
typical integer ops	1	1	1/>2

Valuable resources for detailed analyses

- Software optimization resources by Agner
 - The microarchitecture of Intel, AMD and VIA CPUs: An optimization guide for assembly programmers and compiler makers
 - Instruction tables: Lists of instruction latencies, throughputs and micro-operation breakdowns for Intel, AMD and VIA CPUs
- Intel Intrinsics Guide
- Intel Architecture Code Analyzer (later)

Our code in light of latencies

- in our code, a vfmadd uses the result of the immediately preceding vfmadd
- there are *dependencies* between them
- that was obvious from the source code too

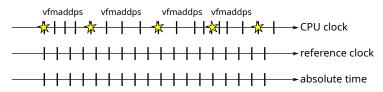

Conclusion:

the loop can't run faster than 4 cycles/iteration

CPU clocks vs. reference clocks

- CPU changes clock frequency depending on the load (DVFS)
- reference clock runs at the same frequency (it is always proportional to the absolute time)
- an instruction takes a specified number of *CPU clocks*, not reference clocks
- the CPU clock is more predictable and thus more convenient for a precise reasoning of the code

Contents

- Introduction
- 2 An endeavor to nearly peak FLOPS
- 3 Latency limit
- Overcoming latency
- 5 Superscalar processors
- 6 A simple yet fairly fast single-core matrix multiply

• increase parallelism (no other ways)!

- increase parallelism (no other ways)!
- you *can't* make a serial chain of dependent computation run faster than determined by latencies

- increase parallelism (no other ways)!
- you *can't* make a serial chain of dependent computation run faster than determined by latencies

• you *can* only increase *throughput*, by running multiple *independent* chains

- increase parallelism (no other ways)!
- you *can't* make a serial chain of dependent computation run faster than determined by latencies

• you *can* only increase *throughput*, by running multiple *independent* chains

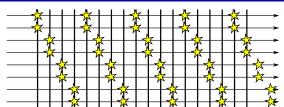

• we expect the following to finish in the same number of cycles as the original one, despite it performs twice as many flops

```
for (i = 0; i < n; i++) {
    x0 = a * x0 + c;
    x1 = a * x1 + c;
}</pre>
```

Increase the number of chains further ...

• we expect to reach peak FLOPS with $\geq 2/(1/4) = 8$ chains (i.e., $nv \geq 8$)

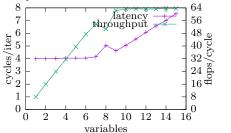

```
long axpy_simd_c( ... ) {
  for (long i = 0; i < n; i++) {
   for (long j = 0; j < nv; j++) {
     X[j] = a * X[j] + c;
  } } }</pre>
```

- note: the above reasoning assumes a compiler's smartness
- in particular, X[j] = a * X[j] + c is compiled into an FMA instruction on registers without load/store instructions (i.e., each of X[0], ..., X[7] gets assigned a register)

Results

a compile-time constant number of variables

```
for (i = 0; i < n; i++) {
  x0 = a * x0 + b;
  x1 = a * x1 + b;
  ...
}
```

chains	clocks/iter	flops/clock
1	4.010	7.979
2	4.003	15.987
3	4.013	23.916

how modern aggressive superscalar processors work:

• instruction decoding goes much ahead of actual executions

- instruction decoding goes much ahead of actual executions
- the actual execution of an instruction does not happen until, and happens as soon as, its operands and execution resources are ready (out of order execution)

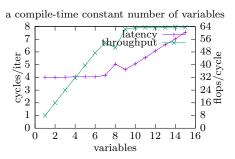

- instruction decoding goes much ahead of actual executions
- the actual execution of an instruction does not happen until, and happens as soon as, its operands and execution resources are ready (out of order execution)
- \bullet \Rightarrow as a crude approximation, performance is constrained by

- instruction decoding goes much ahead of actual executions
- the actual execution of an instruction does not happen until, and happens as soon as, its operands and execution resources are ready (out of order execution)
- \bullet \Rightarrow as a crude approximation, performance is constrained by
 - *latency:* imposed by *dependencies* between instructions

- instruction decoding goes much ahead of actual executions
- the actual execution of an instruction does not happen until, and happens as soon as, its operands and execution resources are ready (out of order execution)
- \bullet \Rightarrow as a crude approximation, performance is constrained by
 - latency: imposed by dependencies between instructions
 - throughput: imposed by execution resources of the processor (e.g., two fmadds/cycle)

A general theory of workload performance on aggressive superscalar machines

- *dependency* constrains how fast a computation can proceed, even if there are infinite number of execution resources
- increase the number of independent computations and you increase *throughput*, until it hits the limit of execution resources

A more general understanding about *throughput* limits

• what you need to know: all instructions have their own throughput limits (just like FMA), due to execution resources

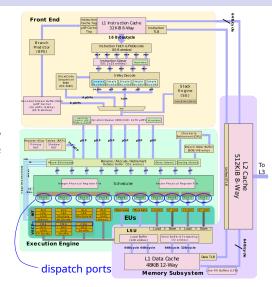

• some examples of recent Intel CPUs

instruction	Broadwell	Skylake SP	Ice Lake SP
fp add/mul/fmadd	2	2	2
load	2	2	2
store	1	1	2
typical integer ops	4	4	4

- e.g., a loop containing 10 load instructions takes $\geq 10/2 = 5$ cycless/iteration
- different but similar instructions may use the same execution resource so may be subject of the same limitation
- a more general reasoning \Rightarrow dispatch ports

Dispatch ports

- each instruction
 (μ-operation) is
 dispatched to a specific
 execution unit through a
 dispatch port
- each port can take only a single operation per cycle
- this determines the throughput of all instructions that go to that port
- with destination ports of instructions, one can calculate the throughput limit of a given loop

Chipwikia - Sunny cove architecture, CC BY-SA 4.0,

 $\verb|https://commons.wikimedia.org/w/index.php?curid=122557706|\\22/41|$

LLVM Machine Code Analyzer (llvm-mca)

- a great tool to analyze the throughput (and latency to some extent) limit
- given a code sequence, it shows
 - latency and
 - dispatch port

of each instruction and, based on them calculates the number of cycles per iteration,

- under some simplifying assumptions
 - the given sequence repeats many times
 - no cache misses (!)
 - no dependencies through memory (load does not depend on earlier stores)
 - no branch misprediction
- ⇒ a great tool to analyze the innermost, straight sequence of instructions without branches (basic blocks)

How to use llvm-mca

• generate assembly (get program.s) by, e.g.,

```
1 clang -03 -mavx512f -mfma ... program.c -S
```

- find the loop you want to analyze in the assembly
- sandwich it by # LLVM-MCA-BEGIN and # LLVM-MCA-END

```
1 # LLVM-MCA-BEGIN
2 .L123
3 ...
4 ...
5 jne .L123
# LLVM-MCA-END
```

• run llvm-mca tool on the assembly code

```
1 llvm-mca program.s
```

How to use llvm-mca

- it shows
 - latency of each instruction
 - dispatch port used by each instruction and how many instructions use each of the dispatch ports (therefore the throughput limit of the loop)
- with --timeline option,

```
llvm-mca --timeline program.s
```

it also shows when each instruction gets decoded, dispatched, and finished (particularly instructive)

Example

• input (assembly)

```
# LLVM-MCA-BEGIN
    .LBB3_8:
2
     \# xmm0 = (xmm1 * xmm0) + xmm2
     vfmadd213sd %xmm2, %xmm1, %xmm0
4
     vfmadd213sd %xmm2, %xmm1, %xmm0
5
     vfmadd213sd %xmm2, %xmm1, %xmm0
6
7
     vfmadd213sd %xmm2, %xmm1, %xmm0
     vfmadd213sd %xmm2, %xmm1, %xmm0
8
     vfmadd213sd %xmm2, %xmm1, %xmm0
     vfmadd213sd %xmm2, %xmm1, %xmm0
10
     vfmadd213sd %xmm2, %xmm1, %xmm0
11
     addq $-8, %rax
12
     ine .LBB3_8
13
    # I.I.VM-MCA-END
14
```

Example

• output (dispatch port used by each instruction)

```
Resource pressure by instruction:
        [1]
            [2] [3] [4] .. [11] Instructions:
            0.990.01 -
                                vfmadd213sd %xmm2, %xmm1, %xmm0
         - - 1.00 -
                               vfmadd213sd %xmm2, %xmm1, %xmm0
5
         - 0.99 0.01 -
                             vfmadd213sd %xmm2, %xmm1, %xmm0
         - - 1.00 -
                               vfmadd213sd %xmm2, %xmm1, %xmm0
         - 1.00 -
                                vfmadd213sd %xmm2, %xmm1, %xmm0
         - - 1.00 -
                                vfmadd213sd %xmm2, %xmm1, %xmm0

Contents

- Introduction
- 2 An endeavor to nearly peak FLOPS
- 3 Latency limit
- 4 Overcoming latency
- 5 Superscalar processors
- 6 A simple yet fairly fast single-core matrix multiply

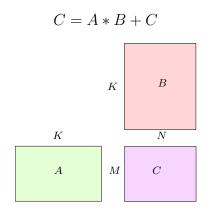

Developing near peak FLOPS matrix multiply

- let's develop a (single core) matrix multiply that runs at fairly good FLOPS on Ice Lake
- it is a great application of the concept you have just learned

Developing near peak FLOPS matrix multiply

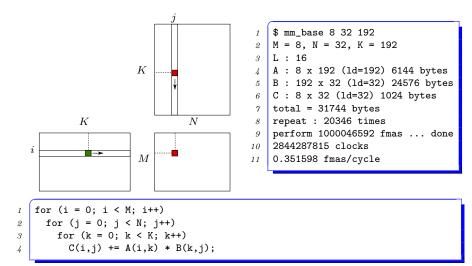

- let's develop a (single core) matrix multiply that runs at fairly good FLOPS on Ice Lake
- it is a great application of the concept you have just learned

A few convenient assumptions

- we add assumptions that M, N, and K are multiple of certain numbers along the way, (don't worry about "remainder" rows/columns)
- we assume matrix sizes are conveniently small (don't worry about memory access cost, which is actually a significant factor to design matrix multiply for larger matrices)
- multiplication of larger (and unknown size) matrices can be built on top of this

Step 1: Baseline code

• it runs at ≈ 2.8 clocks / innermost loop

Step 1: analysis

- latency limit : latency of FMA
 - the reason why it's slightly smaller than 4 is there are some overlaps between different elements of C
 - if you set M = N = 1 and K large, it's almost exactly 4
- throughput limit : not important
- achieved performance : 1000046592 fmas / 2844287815 cycles ≈ 0.4 fmas/cycle

Step 2: Vectorization

```
$ mm_simd 8 32 192
                                           M = 8, N = 32, K = 192
                                          I.: 16
                                        4 A: 8 x 192 (ld=192) 6144 bytes
                                       5 B: 192 x 32 (ld=32) 24576 bytes
                                        6 C: 8 x 32 (ld=32) 1024 bytes
                                          total = 31744 bytes
        K
                            N
                                           repeat : 20346 times
                                           perform 1000046592 fmas ... done
                                           180175475 clocks
i
                   M
                                           5.550404 fmas/cvcle
for (i = 0; i < M; i++)
  for (j = 0; j < N; j += L)
    for (k = 0: k < K: k++)
      C(i,j:j+L) += A(i,k) * B(k,j:j+L);
```

- assumption: N is a multiple of SIMD lanes (L)
- it still runs at ≈ 2.8 clocks / innermost iteration

Step 2: Vectorization

```
$ mm_simd 8 32 192
                                           M = 8, N = 32, K = 192
                                          I.: 16
                                       4 A: 8 x 192 (ld=192) 6144 bytes
                                       5 B: 192 x 32 (ld=32) 24576 bytes
                                        6 C: 8 x 32 (ld=32) 1024 bytes
                                          total = 31744 bytes
        K
                            N
                                           repeat : 20346 times
                                           perform 1000046592 fmas ... done
                                           180175475 clocks
i
                   M
                                           5.550404 fmas/cvcle
for (i = 0; i < M; i++)
  for (j = 0; j < N; j += L)
    for (k = 0: k < K: k++)
      C(i,j:j+L) += A(i,k) * B(k,j:j+L);
```

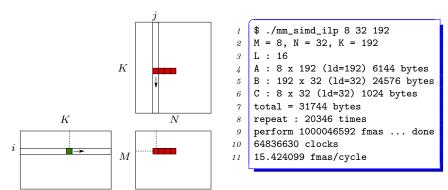

- assumption: N is a multiple of SIMD lanes (L)
- it still runs at ≈ 2.8 clocks / innermost iteration

Step 2: analysis

- the speed is still limited by latency
- the only difference is that each iteration now performs 16 fmas (as opposed to an fma)
- achieved throughput:

 $1000046592 \text{ fmas}/180175475 \text{ cycles} \approx 5.5 \text{ fmas/cycle}$

Step 3: increase parallelism!

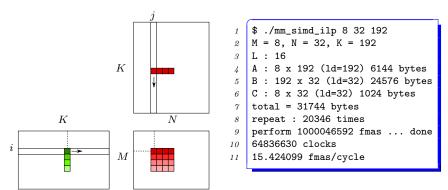

• update bM vector elements of C concurrently

```
for (i = 0; i < M; i += bM)
for (j = 0; j < N; j += L)
for (k = 0; k < K; k++)
for (di = 0; di < bM; di++)
C(i+di,j:j+L) += A(i+di,k) * B(k,j:j+L);</pre>
```

• Ice Lake requires $bM \ge 8$ to reach peak FLOPS

Step 3: increase parallelism!

• update bM vector elements of C concurrently

```
for (i = 0; i < M; i += bM)

for (j = 0; j < N; j += L)

for (k = 0; k < K; k++)

for (di = 0; di < bM; di++)

C(i+di,j:j+L) += A(i+di,k) * B(k,j:j+L);
```

• Ice Lake requires $bM \ge 8$ to reach peak FLOPS

Step 3: analysis

```
for (i = 0; i < M; i += bM)

for (j = 0; j < N; j += L)

for (k = 0; k < K; k++)

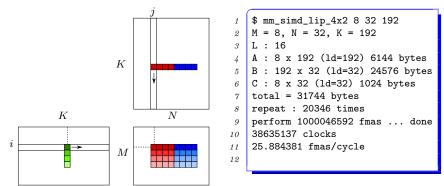

for (di = 0; di < bM; di++)

C(i+di,j:j+L) += A(i+di,k) * B(k,j:j+L);
```

- the for loop at line 4 performs
 - bM loads (broadcasts) for A(i+di,k)
 - 1 load for B(k,j:j+L)
 - bM FMAs
- the load/broadcast throughput = 2 per cycle
- to achieve 2 FMAs/cycle, we must have

the number of broadcast < the number of FMAs

Step 4: Reuse an element of A

• update $bM' \times bN$ block rather than $bM \times 1$

```
for (i = 0; i < M; i += bM')
for (j = 0; j < N; j += bN * L)

for (k = 0; k < K; k++)

for (di = 0; di < bM'; di++)

for (dj = 0; dj < bN * L; dj += L)
C(i+di,j+dj:j+dj+L) += A(i+di,k) * B(k,j+dj:j+L);</pre>
```

Step 4: Analysis

- the for loop at line 4 performs
 - bM' loads (broadcast) for A(i+di,k)
 - bN loads for B(k,j:j+L)
 - $bM' \times bN$ SIMD FMAs
- the minimum requirement for it to achieve the peak FLOPS is $bM' \times bN \ge 8$
- in the experiments, when we set bM' = 8 and bN = 2, it gets 25 fmas/cycle ($\approx 80\%$ of the peak)
- we need to note that this happens only when the matrix is small (M = 8, N = 32, K = 192) and we repeat it many times
- the issue for large matrices will be the next topic

Takeaways (1)

- peak FLOPS of many recent Intel CPUs = "execute two fmadds every cycle" (no other combinations)
 - other processors have different limits, but the basics is the same
 - cf. NVIDIA GPUs = "execute two warps (each doing fmadd) every cycle"
- single-core performance is not about reducing the number of instructions
- it's about how to increase parallelism
 - $CPU : SIMD \times ILP$
 - GPU: threads, threads, ...
 - but the internal machinery is similar (warp \approx SIMD, ILP \sim warps in an SM)
 - how they expose parallelism to the programmer is different

Takeaways (2)

 \bullet dependent instructions in cur latencies and hinder parallelism
